<p>(54) Title: MANAGEMENT OF COMPUTER WORKSTATIONS</p> <p>(57) Abstract</p> <p>A method of managing a plurality of computer workstations interconnected by a network, the workstations including at least one policy group. The method includes the steps of receiving data relating to the policy group definition and generating a program representative of the policy group definition data. The generated program is sent to each of the plurality of workstations and the workstations instructed to check, by employing the program, whether or not each respective workstation belongs or does not belong to the at least one policy groups. The results of the checking step from each work station are returned to at least one managing station.</p> 		

MANAGEMENT OF COMPUTER WORKSTATIONS

The subject of this application is concerned with modern networks of computers. With the advent of reliable
5 Local Area Networks (LANs) and good quality Wide Area Networks (WANs) it has been possible to interconnect low cost powerful personal computers and file / print server equipment. Such networks of computers have grown very quickly in recent years so that it is not uncommon to find
10 networks ranging from thousands to tens of thousands of computer (nodes) all within the same commercial organisation. Companies usually develop such networks to cover a number of main sites which will be served by LANs and interconnected via WAN links.

15 This structure is in marked contrast to the structure of data networks of 10 years ago where computer terminals were connected directly (or via concentrators) to one or a very few large mainframe computers.

Not only does this change represent a major difference
20 in technology, but it also gives rise to differences in operating principles. In the old mainframe case, all services were provided and controlled centrally from the company's IT and Operations departments; whereas now there is a strong tendency to decentralise and for individual
25 departments become responsible for their own workstation PCs. In any event, no central control is implied or (usually) imposed on LANs and their connected systems.

Management systems for controlling the network infrastructure of LAN/WAN networks are frequently to be
30 found but to date, few (if any) of these address the problem of managing workstations and their servers (fig 1). A major problem comes about from the fact that each PC is independent of the others and thus may be configured differently and without reference to them. Each may contain
35 different software suites as well as different hardware. However, since they are all using a common data infrastructure (the LAN/WAN) these differences can give

agent residing in) each workstation will check periodically whether or not it fulfils any group membership and if so it will transmit a trap or event message to the network management station. This in turn on receiving these traps will update its database to reflect this. Thus, since the membership of each group is checked independently by each workstation, the effect is one of producing an inventory in real time of network status. Policies can therefore be managed with an assurance of accurate and timely information.

The novelty of the above approach is in respect of the fact that the decisions for group membership are taken by each workstation itself and independently of any others. In order to do this, it is necessary that the stations are capable of receiving and processing the definition information, be it in the form of a definition file or in the form of an executable script or program which is generated at the management station. This in turn implies the presence of some form of management agent in the workstations, and a communications sub-system which can send to and receive transmissions from the management system, which itself will update its database to record any changes.

One example of the present invention will now be described with reference to the accompanying drawings, in which:

Figure 1 shows a computer network;

Figure 2 shows a network management system employing the invention; and

Figure 3 is a flow diagram of an operation according to the invention.

Figure 1 shows a standard node computer network which has plural interconnected user workstations. The workstations are managed from a main network management station.

The problem cited above of managing the workstations, can be seen in this context as one of updating (reading

to manage this information on larger scale management systems because of the extent of the information, the numbers of nodes involved and the inter-relationships which may exist between co-operating network devices 11.

5 Manageable devices 11 are those end stations which can be interrogated and updated from the management system 12. This interrogation and updating is performed by sending messages (from the communications sub-system 4) to control programs (known as agents) which reside and are always
10 active locally in the end stations 11. These agents are very common in network devices (such as bridges and routers) but are only just becoming available for user workstations.

 The steps required for the implementation of the
15 invention are shown in fig 3. The actions are initiated by a network administrator who will decide on the group membership conditions and configure his management station 12 accordingly (step 1). This is then compiled into scripts or programs (step 2) which are sent to all workstation
20 agents on the network 10 (step 3). Note that normally there will be many group definitions active at any one time. At each workstation 11, on receiving a new group definition, the local agent will add it to his list of active group conditions and periodically will check the
25 workstation 11 to see if any changes have taken place which affect the membership conditions (step 4). The rate at which this checking (polling) takes place is given by the script, since some conditions are more dynamic than others. A typical check on available disk space, for example, might
30 be once every 15 seconds, whereas that for installed software need only be once every 10 minutes. Note that the agent will perform these checks independently of the workstation 11 being connected to the network 10, and will signal them as and when it is reconnected. This is
35 particularly useful for portable PCs.

 Whenever a change is detected which affects the membership of one or more defined groups, the agent causes

CLAIMS

1. A method of managing a plurality of computer workstations interconnected by a network, the workstations including at least one policy group, the method including the steps of:
- 5 receiving data relating to the policy group definition;
- generating a program representative of the policy group definition data;
- 10 sending the generated program to each of the plurality of workstations;
- instructing the workstations to check, by employing the program, whether or not each respective workstation belongs or does not belong to the at least one policy groups; and
- 15 returning the results of the checking step from each work station to at least one managing station.
2. A method according to claim 1, wherein the policy group definition data is received at a remote location.
- 20 3. A method according to claim 1 or claim 2, wherein the generated program is generated at a remote location.
- 25 4. A method according to any of claims 1 to 3, wherein the checking step is performed regardless of whether the workstation is connected to a network or not.
- 30 5. A method according to any of the preceding claims, wherein the generated program is altered in response to the returned results.
